Appendix A: Summary of Experimental Conditions

Table 1 describes the 44 experimental conditions included in the model comparison, including the number of trials, the number of words presented per trial (Words/Trial), the number of referents presented per trial (Objects/Trial), the number of to-be-learned word-referent pairs (Items), people's overall mean accuracy (p(o|w) across all intended w-o mappings) in each condition (Accuracy), the standard deviation of performance (SD), and the number of participants per condition (N).

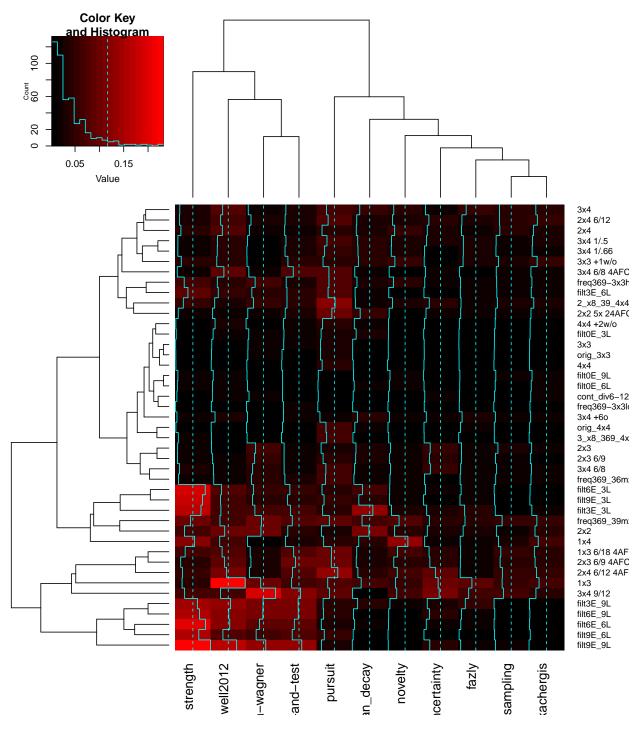

Appendix B: Clustering experiments and models by misfit

The table below shows model fit (SSE; sum of squared error) for each experimental condition.

Model fit x Experiment table? maybe clustered...? (to show most similar models, and most similar experiments?)

Table 1: Summary of modeled datasets.

Takeaways: Some experimental conditions are hard for particular models to fit. For example, the strength-biased model has particular difficulty with the filt conditions¹ (Kachergis et al., 2012), which present a group of word-referent pairs early in training which then systematically co-occur with particular novel late-stage word-referent pairs, testing how strictly learners will maintain a mutual exclusivity (ME) constraint. The Trueswell2012 model also shows greater misfit in most of these conditions (except for the filtXE_3L conditions, which have only 3 repetitions of the late-stage pairings, and thus do not overwhelm learners' ME bias).

 $^{^1\}mathrm{Except}$ for the $\mathtt{filt0E}$ _ conditions, which consist only of the late-stage pairs, with no early stage.

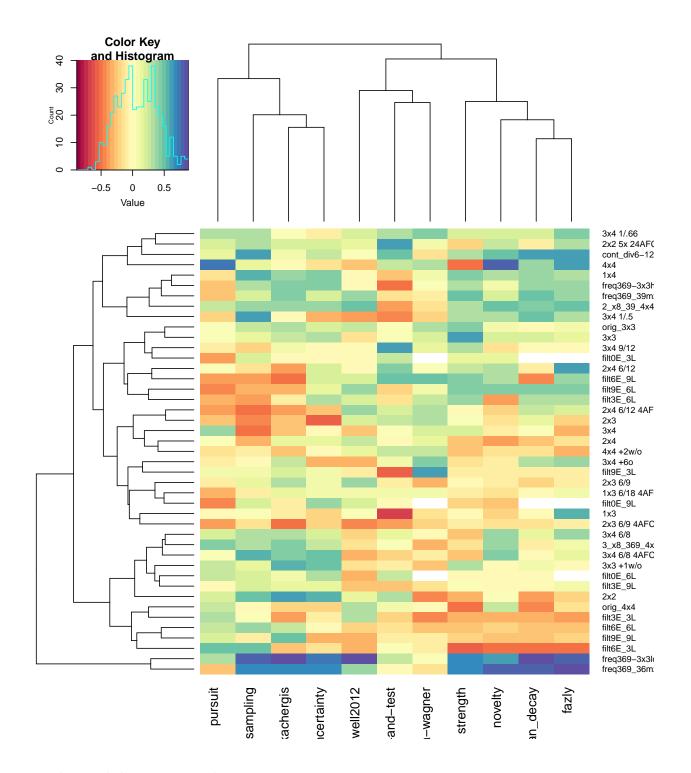

On the other hand, many experimental conditions are nearly equally well fit by all models, especially those that have a fixed number of repetitions per word-referent pair (e.g., 3x3, 4x4,)

Other ideas:

- Find experiment with maximal discrimination between the models? (highest SD of fit?)
- Find experiment that each model best predicts? and worst predicts?

Correlation of model predictions with item perforance per condition

Each cell displays the correlation coefficient of model vs. human item-level performance in a given experimental condition.

Each Model's Best- and Worst-Fitting Experiment

Which experiments are models best fitting?

Best and worst fitting models per experiment

(Could order conditions by how much they discriminate models?)

Model	best	worst	best_cond	worst_cond
